Abstract

We summarize the known methods of producing a non-supercompact strongly compact cardinal and describe some new variants. Our Main Theorem shows how to apply these methods to many cardinals simultaneously and exactly control which cardinals are supercompact and which are only strongly compact in a forcing extension. Depending upon the method, the surviving non-supercompact strongly compact cardinals can be strong cardinals, have trivial Mitchell rank or even contain a club disjoint from the set of measurable cardinals. These results improve and unify Theorems 1 and 2 of [6], due to the first author.

1 Introducing the Main Question

The notions of strongly compact and supercompact cardinal are very close, so close that years ago it was an open question whether they were equivalent. When Solovay first defined the supercompact

[‡]The second author's research was partially supported by PSC-CUNY and NSF grants.

cardinals—witnessed by *normal* fine measures on $P_\kappa(\lambda)$, rather than merely fine measures, which give rise only to strong compactness—he had simply added the kind of normality assumption that set theorists were accustomed to getting for free in the case of measurable cardinals. And so he and many others expected that these notions would be equivalent. Confirming evidence for this initial expectation was found in the models constructed by Kimchi and Magidor [23] (see [2] and [12] for a modern account), where the two notions do coincide.

But set theorists now know that the two notions are not equivalent (although it is unknown whether they are equiconsistent), and we have a variety of ways of producing non-supercompact strongly compact cardinals. Let us classify these different methods into five general categories.

1. *The purely ZFC method.* This is historically the first way in which non-supercompact strongly compact cardinals were exhibited, and can be contrasted with the forcing results, which show merely the relative consistency of inequivalence. Its foundation is the observation by Solovay’s student Telis Menas [27] that any measurable limit of strongly compact cardinals is itself strongly compact, but the least such cardinal (and many more) cannot be supercompact. A related observation, given in the context of a supercompact limit of supercompact cardinals by the first author in [5], is that the least cardinal κ (and many more) that is κ^+ , κ^{++} , κ^{+++} , etc. supercompact and is also a limit of strongly compact cardinals is strongly compact but isn’t (fully) supercompact.¹
2. *The Menas forcing method.* Menas used his aforementioned result in [27] to exhibit the inequivalence of strong compactness and supercompactness much lower in the hierarchy, by forcing over a model with a measurable limit of supercompact cardinals and producing a model where the least strongly compact cardinal is not supercompact. Jacques Stern, in unpublished work, generalized these ideas to create a model in which the first two strongly compact cardinals are not supercompact. The first author, in [6], also used these ideas in a

¹The strong compactness measures for the limit cardinal κ are obtained simply by integrating the smaller strong compactness measures for cardinals below κ with respect to a fixed measure on κ . Conversely, the least such cardinal κ must have limited supercompactness in M for any embedding $j : V \rightarrow M$ having critical point κ , by the minimality of $j(\kappa)$ there; so κ cannot be supercompact.

way we will discuss in greater detail below. The second author combined these ideas with fast function forcing in Corollary 4.3 of [20], where he showed that *any* strongly compact cardinal κ can be forced to be a non-supercompact strongly compact cardinal. This was accomplished by showing that any strongly compact cardinal κ can be made indestructible by the forcing to add a club $C \subseteq \kappa$ containing no measurable cardinals. After such forcing, κ clearly cannot be supercompact, or even have nontrivial Mitchell rank. The technique allows one to add coherent sequences of clubs to smaller cardinals which reflect at their inaccessible limit points.

3. *The method of iterated Prikry forcing.* Inspired by Menas' work mentioned in (1) and (2) above, Magidor [26] provided a technique for producing non-supercompact strongly compact cardinals, the method of iterated Prikry forcing, which yielded a striking result: a model in which the least measurable cardinal—which obviously cannot be supercompact—is strongly compact. Magidor's ground model required no GCH assumptions and began with only a strongly compact cardinal. These ideas have also been used by the first author in [5] and [3] and by Abe in [1] to create further examples of non-supercompact strongly compact cardinals. In addition, a modification of this forcing notion was discovered by Gitik in [16], where a different proof of Magidor's theorem is essentially given in Section 4, pages 302–303, starting with a ground model satisfying GCH and containing a strongly compact cardinal, using an iteration of Prikry forcing containing Easton supports (as opposed to finite support in the first coordinate and full support in the second coordinate in the Magidor iteration of Prikry forcing). Gitik's technique was later modified by the first author and Gitik in [10], where, starting from a ground model satisfying GCH and containing a supercompact cardinal, they produced an assortment of models in which the least strongly compact cardinal κ isn't supercompact yet has its strong compactness and degree of supercompactness fully indestructible under κ -directed closed forcing. In one of the models constructed, the least strongly compact cardinal is also the least measurable cardinal, yet indestructible.

4. *The method of iteratively adding non-reflecting stationary sets of ordinals.* While Magidor's

result mentioned in (3) above was very exciting, making strong compactness and supercompactness seem very far apart, it unfortunately could not be used to handle more than one strongly compact cardinal. This was because Prikry forcing above a strongly compact cardinal adds a weak square sequence, which destroys the strong compactness of the smaller cardinal. Magidor overcame this difficulty by inventing yet another technique for producing non-supercompact strongly compact cardinals. Rather than iterating Prikry forcing below a supercompact cardinal κ , he now iterated instead the forcing to add a non-reflecting stationary set of ordinals to every measurable cardinal below κ . This iteration destroys all the measurable cardinals below κ , and yet κ remains strongly compact in the extension. Then, using this technique, Magidor constructed for each natural number n a model where the first n measurable cardinals are strongly compact (but clearly not supercompact), beginning with a model having n indestructible supercompact cardinals. Unfortunately, Magidor's method does not seem to work in the infinite case, and the question of the relative consistency of the first ω measurable cardinals all being strongly compact is open. This theorem and technique, although unpublished by Magidor, appeared in [8], along with a related generalization due to the first author and Cummings. Further generalizations of Magidor's method using an iteration of the forcing for adding non-reflecting stationary sets of ordinals to produce additional examples of non-supercompact strongly compact cardinals can be found in [4] and [9], and a modification of this method using an iteration of the forcing for adding Cohen subsets to produce additional examples of non-supercompact strongly compact cardinals can be found in [11]. Another exposition of Magidor's method can be found in [7], as well as Lemma 8 of this paper.

5. *The method of Radin forcing.* This unpublished technique is due to Woodin, and was invented by him and modified by Magidor at the January 7-13, 1996 meeting in Set Theory held at the Mathematics Research Institute, Oberwolfach, Germany to give a proof of the theorem of [3] from only one supercompact cardinal, instead of hypotheses on the order of a supercompact limit of supercompact cardinals. A further proof of this theorem, employing

only one supercompact cardinal, is given in [8].

We mention all these methods for turning a supercompact cardinal into a non-supercompact strongly compact cardinal because in this article we seek uniform methods to control exactly in this way any given class of supercompact cardinals simultaneously. Specifically, we seek an affirmative answer to the following question.

Main Question 1 *Given a class of supercompact cardinals, can one force them to be strongly compact and not supercompact while fully preserving all other supercompact cardinals and creating no new strongly compact or supercompact cardinals?*

We are pleased to announce an affirmative answer to this question for a broad collection of classes. Yes, one can force any given class of supercompact cardinals $\mathcal{A}$ to become strongly compact and not supercompact while fully preserving all other supercompact cardinals and creating no new strongly compact or supercompact cardinals, provided that $\mathcal{A}$ does not contain certain kinds of complicated limit points. In particular, if there are no supercompact limits of supercompact cardinals (or merely no supercompact limits of supercompact limits of supercompact cardinals), then any class $\mathcal{A}$ of supercompact cardinals can be exactly controlled in this way. Indeed, our control over the non-supercompact strongly compact cardinals is even greater than requested in the Main Question, for we can ensure that they remain strong cardinals in the extension or alternatively, that as measurable cardinals they have trivial Mitchell rank or even contain a club containing no measurable cardinals. Specifically, we will prove the following.

Main Theorem 2 *Suppose that $\mathcal{A}$ is a subclass of the class $\mathcal{K}$ of supercompact cardinals containing none of its limit points. Then there is a forcing extension $V^{\mathbb{P}}$ in which the cardinals in $\mathcal{A}$ remain strongly compact but become non-supercompact, while the cardinals in $\mathcal{K} - \mathcal{A}$ remain fully supercompact. In addition, no new strongly compact or supercompact cardinals are created. In $V^{\mathbb{P}}$, the class of strongly compact cardinals is composed of $\mathcal{K}$ together with its measurable limit points. Depending on the choice of $\mathbb{P}$, the cardinals of $\mathcal{A}$ become strong cardinals in $V^{\mathbb{P}}$ or contain a club*

disjoint from the measurable cardinals there, respectively. Finally, if κ is a measurable limit of $\mathcal{A}$ at which the GCH holds in V , then both the GCH at κ and κ 's measurability are preserved in $V^{\mathbb{P}}$.

Main Corollary 3 *If there is no supercompact limit of supercompact cardinals, then the answer to the Main Question is Yes. In particular, an affirmative answer to the Main Question is relatively consistent with the existence of many supercompact cardinals, even a proper class of supercompact cardinals.*

The point here is that if there is no supercompact limit of supercompact cardinals, then every class $\mathcal{A}$ satisfies the hypothesis of the theorem.

By iterating the result of the Main Theorem, we are able to generalize it to make almost the same conclusions with any class $\mathcal{A}$ having finite Cantor-Bendixon rank.

Generalized Main Theorem 4 *The main conclusions of the Main Theorem 2 hold for any class $\mathcal{A} \subseteq \mathcal{K}$ having finite Cantor-Bendixon rank. That is, for any such $\mathcal{A}$, there is a forcing extension $V^{\mathbb{P}}$ in which the cardinals of $\mathcal{A}$ become strongly compact but not supercompact, while the cardinals in $\mathcal{K} - \mathcal{A}$ remain fully supercompact. In addition, no new strongly compact or supercompact cardinals are created. In $V^{\mathbb{P}}$, the class of strongly compact cardinals is composed of $\mathcal{K}$ together with its measurable limit points. Finally, if κ is a measurable limit of $\mathcal{A}$ at which the GCH holds in V , then both the GCH at κ and κ 's measurability are preserved in $V^{\mathbb{P}}$.*

And the Generalized Main Theorem comes also with its own generalized corollary:

Generalized Main Corollary 5 *If the class of supercompact cardinals has finite Cantor-Bendixon rank, then the answer to the Main Question 1 is Yes. Therefore, an affirmative answer to the question is relatively consistent with the existence of a proper class of supercompact limits of supercompact limits of supercompact cardinals, and supercompact limits of these, and so on.*

The first author made substantial progress in [6] on a question related to the Main Question, when he proved that we already have a fine control over the pattern that the supercompact cardinals make as a subclass of the strongly compact cardinals. Specifically, in Theorem 1 of [6], using ideas of

Menas from [27] in tandem with those from [2], he begins with an inaccessible limit Ω of measurable limits of supercompact cardinals, and produces a model where the pattern of the supercompact cardinals as a subset of the general class of (strongly) compact cardinals follows any prescribed function $f : \Omega \rightarrow 2$ in the ground model.² The resulting non-supercompact strongly compact cardinals there have trivial Mitchell rank. In his argument, somewhat like the earlier arguments of Menas and Stern, the cardinals that eventually become strongly compact but not supercompact begin as measurable limits of supercompact cardinals in the ground model. Necessarily, therefore, many supercompact cardinals are destroyed along the way. The main result of this article overcomes this difficulty.

Our Main Theorem provides a new proof of Theorem 1 of [6] and provides a substantial reduction in the hypotheses used to prove Theorem 1 of [6], from an inaccessible limit of measurable limits of supercompact cardinals to a proper class of supercompact cardinals. It also allows us to provide a uniform proof of both a strengthened version of Theorem 1 of [6] and a more general, stronger version of Theorem 2 of [6], since Theorem 2 of [6] extends Theorem 1 of [6] to the situation encompassing a cardinal κ which is a supercompact limit of supercompact cardinals. Further, Theorem 1 of [7] can now be derived as a corollary of our Main Theorem.

Let us conclude this section with some preliminary information and basic definitions. Essentially, our notation and terminology are standard, and when this is not the case, it will be clearly noted. For $\alpha < \beta$ ordinals, $[\alpha, \beta]$, $[\alpha, \beta)$, $(\alpha, \beta]$, and (α, β) are as in standard interval notation.

When forcing, $q \geq p$ will mean that q is stronger than p . If G is V -generic over $\mathbb{P}$, we will use both $V[G]$ and $V^{\mathbb{P}}$ to indicate the universe obtained by forcing with $\mathbb{P}$. If $\mathbb{P}$ is an iteration, then $\mathbb{P}_\alpha$ is the forcing up to stage α . When κ is inaccessible and $\mathbb{P} = \langle \langle \mathbb{P}_\alpha, \dot{\mathbb{Q}}_\alpha \rangle : \alpha < \kappa \rangle$ is an Easton support iteration of length κ which at stage α performs some nontrivial forcing based on the ordinal δ_α , then we will say that δ_α is in the field of $\mathbb{P}$. If $x \in V[G]$, then $\dot{x}$ will be a term in V for x . We may, from time to time, confuse terms with the sets they denote and write x when we actually mean $\dot{x}$, especially when x is some variant of the generic set G , or x is in the ground model V .

²The proof could be modified to omit the cardinal Ω , and treat $f : Ord \rightarrow 2$, through the use of proper classes.

If κ is a cardinal and $\mathbb{P}$ is a partial ordering, $\mathbb{P}$ is κ -directed closed if for every directed subset $D \subseteq \mathbb{P}$ of size less than κ (where D is directed if every two elements of D have an upper bound in $\mathbb{P}$) has an upper bound in $\mathbb{P}$. The partial order $\mathbb{P}$ is κ -strategically closed if in the two person game in which the players construct an increasing sequence $\langle p_\alpha : \alpha \leq \kappa \rangle$, where player I plays odd stages and player II plays even and limit stages (choosing the trivial condition at stage 0), then player II has a strategy which ensures the game can always be continued. Note that if $\mathbb{P}$ is κ^+ -directed closed, then $\mathbb{P}$ is κ -strategically closed. Also, if $\mathbb{P}$ is κ -strategically closed and $f : \kappa \rightarrow V$ is a function in $V^\mathbb{P}$, then $f \in V$. $\mathbb{P}$ is $\prec\kappa$ -strategically closed if in the two person game in which the players construct an increasing sequence $\langle p_\alpha : \alpha < \kappa \rangle$, where player I plays odd stages and player II plays even and limit stages (again choosing the trivial condition at stage 0), then player II has a strategy which ensures the game can always be continued.

If X is a set of ordinals, then X' is the set of limit points of X . The Cantor-Bendixon derivatives of a set X are defined by iteratively removing isolated points. One begins with the original set $X^{(0)} = X$, removes isolated points at successor stages by keeping only the limit points $X^{(\alpha+1)} = X^{(\alpha)} \cap (X^{(\alpha)})'$, and takes intersections at limit stages $X^{(\lambda)} = \bigcap_{\alpha < \lambda} X^{(\alpha)}$. For any class of ordinals X , if $X^{(\alpha)} = \emptyset$ for some α , then the Cantor-Bendixon rank of X is the least such α . The Cantor-Bendixon rank of a point γ in X is the largest β such that $\gamma \in X^{(\beta)}$, that is, the stage at which γ becomes isolated.

In this paper, we will use non-reflecting stationary set forcing $\mathbb{P}_{\eta,\lambda}$. Specifically, if $\eta < \lambda$ are both regular cardinals, then conditions in $\mathbb{P}_{\eta,\lambda}$ are bounded subsets $s \subset \lambda$ consisting of ordinals of cofinality η such that for every $\alpha < \lambda$, the initial segment $s \cap \alpha$ is non-stationary in α , ordered by end-extension. It is well-known that if G is V -generic over $\mathbb{P}_{\eta,\lambda}$ (see [13], [7], or [23]) and the GCH holds in V , then in $V[G]$, the set $S = S[G] = \bigcup G \subseteq \lambda$ is a non-reflecting stationary set of ordinals of cofinality η , the bounded subsets of λ are the same as those in V , and cardinals, cofinalities and the GCH have been preserved. It is virtually immediate that $\mathbb{P}_{\eta,\lambda}$ is η -directed closed. It follows from Theorem 4.8 of [29] that the existence of a non-reflecting stationary subset of λ , consisting of ordinals of cofinality η , implies that no cardinal $\delta \in (\eta, \lambda]$ is λ strongly compact. Thus, iterations

of this forcing provide a way to destroy all strongly compact cardinals in an interval.

We assume familiarity with the large cardinal notions of measurability, strongness, strong compactness, and supercompactness. Interested readers may consult [22] for further details. We mention only that a cardinal κ is $<\lambda$ supercompact iff it is δ supercompact for every cardinal $\delta < \lambda$. We will always identify an ultrapower with its Mostowski collapse. We note that a measurable cardinal κ has trivial Mitchell rank if there is no embedding $j : V \rightarrow M$ for which $\text{cp}(j) = \kappa$ and $M \models \text{“}\kappa \text{ is measurable”}$. An ultrafilter $\mathcal{U}$ generating this sort of embedding will be said to have trivial Mitchell rank as well. Ultrafilters of trivial Mitchell rank always exist for any measurable cardinal κ . Also, unlike [22], we will say that the cardinal κ is λ strong for an ordinal $\lambda > \kappa$ if there is $j : V \rightarrow M$ an elementary embedding having critical point κ so that $j(\kappa) > |V_\lambda|$ and $V_\lambda \subseteq M$. As always, κ is strong if κ is λ strong for every $\lambda > \kappa$.

As in [20] we define the lottery sum of a collection $\mathcal{C}$ of partial orderings to be $\oplus \mathcal{C} = \{\langle \mathbb{Q}, q \rangle : \mathbb{Q} \in \mathcal{C} \text{ and } q \in \mathbb{Q}\} \cup \{0\}$, ordered with 0 below everything and $\langle \mathbb{Q}, q \rangle \leq \langle \mathbb{Q}', q' \rangle$ iff $\mathbb{Q} = \mathbb{Q}'$ and $q \leq q'$. (This is equivalent simply to taking the product of the corresponding Boolean algebras.) Forcing with $\oplus \mathcal{C}$ amounts to selecting a particular partial ordering $\mathbb{Q}$ from $\mathcal{C}$, the “winning partial ordering”, and then forcing with it. The lottery preparation of [20] proceeds by iterating these lottery sums, and has proved to be useful for obtaining indestructibility even in a large cardinal context in which one lacks a Laver function.

Finally, we will say that an elementary embedding $k : V \rightarrow N$ with critical point κ has the λ -cover property when for any $x \subseteq N$ with $|x| \leq \lambda$, there is some $y \in N$ so that $x \subseteq y$ and $N \models \text{“}|y| < k(\kappa)”}$. A suitable cover of $j \restriction \lambda$ generates a fine measure over $P_\kappa(\lambda)$ and conversely, so one can easily deduce that such an embedding exists iff κ is λ strongly compact (see Theorem 22.17 of [22]).

2 Two Useful Propositions

The proof of the Main Theorem will proceed by taking large products of the forcing that transforms a given supercompact cardinal into a non-supercompact strongly compact cardinal. The particular

iterations we will use to accomplish this are given in the proofs of the following two propositions.

Proposition 6 *If κ is supercompact, then regardless of the number of large cardinals in the universe, there is a forcing extension $V^{\mathbb{P}}$ in which κ is strongly compact, $2^\kappa = \kappa^+$ and κ has trivial Mitchell rank. For any regular $\eta < \kappa$, such a partial ordering $\mathbb{P}$ can be found which is η -directed closed and of cardinality at most 2^κ . Indeed, if $2^\kappa = \kappa^+$ in the ground model, then $\mathbb{P}$ can have cardinality κ . Furthermore, $\mathbb{P}$ can be defined so as to destroy any strongly compact cardinal in the interval (η, κ) .*

Proposition 7 *Suppose that κ is supercompact and $\eta < \kappa$. Then regardless of the number of large cardinals in the universe, there is a forcing extension $V^{\mathbb{P}}$ in which κ becomes a non-supercompact strongly compact cardinal, $2^\kappa = \kappa^+$ and all other supercompact cardinals above η are preserved. Such a partial ordering $\mathbb{P}$ can be found which is η -directed closed and of cardinality at most 2^κ . Indeed, if $2^\kappa = \kappa^+$ in the ground model, then $\mathbb{P}$ can have cardinality κ . Depending upon the exact choice of $\mathbb{P}$, the cardinal κ will either contain a club disjoint from the measurable cardinals (and hence have trivial Mitchell rank) or become a strong cardinal, respectively. Furthermore, every strongly compact cardinal in $V^{\mathbb{P}}$ in the interval $(\eta, \kappa]$ is either supercompact in V or a measurable limit of supercompact cardinals in V .*

These two propositions are closely related to [20, Corollary 4.3]. In particular, if one omits the last sentence of Proposition 6 (which will not actually be relevant in our application), it is an immediate consequence of [20, Corollary 4.3], which has both a weaker hypothesis and a stronger conclusion: one can add to any strongly compact cardinal κ a club disjoint from the measurable cardinals while preserving the strong compactness of κ and neither creating nor destroying any measurable cardinals. This method also arises in the proof of Proposition 7, in Lemma 11. And the forcing of [20, Corollary 4.3] can be a component of the product forcing used to prove the Main Theorem in the situation when there are no supercompact limits of supercompact cardinals (which is also true for the forcing given in Proposition 6 or the forcing used in the proof of Theorem 1 of [9]). We give the alternative proof of Proposition 6 here because of the extra property that

it destroys all strongly compact cardinals in the interval (η, κ) , which may find an application elsewhere.

We would like to call special attention to the fact that both Propositions 6 and 7 can be applied over a universe with many large cardinals. This contrasts sharply with Magidor's forcing to create a non-supercompact strongly compact cardinal by adding non-reflecting stationary sets of ordinals to every measurable cardinal below the supercompact cardinal κ or the modifications of this method given in [4] and [8], which seem to require severe restrictions on the type of large cardinals above κ .³ Also, the forcing of Proposition 7 has been explicitly designed to preserve the supercompactness of all cardinals above η except for κ , which distinguishes it from the other partial orderings we have mentioned.

Let's now prove Proposition 6.

Proof: Let $V \models \text{“ZFC} + \kappa \text{ is supercompact”}$, and suppose $\eta < \kappa$ is regular. By forcing if necessary, we may assume without loss of generality that $2^\kappa = \kappa^+$ in V . This is done by simply using the Laver preparation from η up to κ (e.g., the version given in [2]), followed by the forcing which adds a Cohen subset to κ^+ , thereby ensuring $2^\kappa = \kappa^+$. This combined forcing also preserves all supercompact cardinals above η and has cardinality 2^κ . By the Gap Forcing Theorem of [18] and [19], if this combined forcing begins by adding a Cohen subset to η , it creates no new supercompact or measurable cardinals above η .

Let $\mathbb{P}$ be the Easton support forcing κ -iteration which adds to every measurable limit of strong cardinals $\sigma \in (\eta, \kappa)$ a non-reflecting stationary set of ordinals of cofinality η . It is not difficult to see that $\mathbb{P}$ has cardinality κ , so $V^\mathbb{P} \models \text{“}2^\kappa = \kappa^+\text{”}$. Thus, the following three lemmas complete the proof of Proposition 6.

Lemma 8 $V^\mathbb{P} \models \text{“}\kappa \text{ is strongly compact”}$.

Proof: We use Magidor's method for preserving strong compactness mentioned at the beginning of this paper. Let $\lambda > \kappa$ be an arbitrary singular strong limit cardinal of cofinality at least κ , and let $k_1 : V \rightarrow M$ be an elementary embedding witnessing the λ supercompactness of κ so that

³The modification of Magidor's method given in [9] also can be applied over a universe with many large cardinals.

$M \models \text{“}\kappa \text{ isn't } \lambda \text{ supercompact”}$. By the choice of λ , the cardinal κ is $<\lambda$ supercompact in M . Since $\lambda \geq 2^\kappa$, we know κ is measurable in M . Therefore, there is a normal measure of trivial Mitchell rank over κ in M , yielding an embedding $k_2 : M \rightarrow N$, with critical point κ , such that $N \models \text{“}\kappa \text{ isn't measurable”}$. In addition, as $\lambda \geq 2^\kappa$, Lemma 2.1 of [9] and the succeeding remark imply that in both V and M , κ is a strong cardinal which is also a limit of strong cardinals, and in fact, in both V and M , κ carries a normal measure concentrating on strong cardinals.

It is easy to verify that the composed embedding $j = k_2 \circ k_1 : V \rightarrow N$ has the λ -cover property, and therefore witnesses the λ strong compactness of κ . We will show that j lifts to $j : V^\mathbb{P} \rightarrow N^{j(\mathbb{P})}$. Since this lifted embedding will witness the λ strong compactness of κ in $V^\mathbb{P}$, this will prove Lemma 8.

To do this, factor $j(\mathbb{P})$ as $\mathbb{P} * \dot{\mathbb{Q}} * \dot{\mathbb{R}}$, where $\dot{\mathbb{Q}}$ is a term for the portion of $j(\mathbb{P})$ from stage κ up to and including stage $k_2(\kappa)$, and $\dot{\mathbb{R}}$ is a term for the rest of $j(\mathbb{P})$, from stage $k_2(\kappa) + 1$ up to $j(\kappa)$. Since $N \models \text{“}\kappa \text{ isn't measurable”}$, we know that $\kappa \notin \text{field}(\dot{\mathbb{Q}})$. Thus, the field of $\dot{\mathbb{Q}}$ is composed of all N -measurable limits of N -strong cardinals in the interval $(\kappa, k_2(\kappa)]$ (so $k_2(\kappa)$ is in the field of $\dot{\mathbb{Q}}$), and the field of $\dot{\mathbb{R}}$ is composed of all N -measurable limits of N -strong cardinals in the interval $(k_2(\kappa), k_2(k_1(\kappa)))$.

Let G_0 be V -generic over $\mathbb{P}$. We will construct in $V[G_0]$ an $N[G_0]$ -generic object G_1 over $\mathbb{Q}$ and an $N[G_0][G_1]$ -generic object G_2 over $\mathbb{R}$. Since $\mathbb{P}$ is an Easton support iteration of small forcing, with a direct limit at stage κ and no forcing right at stage κ , the construction of G_1 and G_2 ensures that $j''G_0 \subseteq G_0 * G_1 * G_2$. It follows that $j : V \rightarrow N$ lifts to $j : V[G_0] \rightarrow N[G_0][G_1][G_2]$ in $V[G_0]$.

To build G_1 , note that since k_2 is generated by an ultrafilter $\mathcal{U}$ over κ and $2^\kappa = \kappa^+$ in both V and M , we know $|k_2(2^\kappa)| = |k_2(\kappa^+)| = |\{f : f : \kappa \rightarrow \kappa^+ \text{ is a function}\}| = |[\kappa^+]^\kappa| = \kappa^+$. Thus, as $N[G_0] \models \text{“}|\wp(\mathbb{Q})| = k_2(2^\kappa)\text{”}$, we can let $\langle D_\alpha : \alpha < \kappa^+ \rangle$ be an enumeration in $V[G_0]$ of the dense open subsets of $\mathbb{Q}$ present in $N[G_0]$. Since the κ closure of N with respect to either M or V implies that the least element of the field of $\mathbb{Q}$ is above κ^+ , the definition of $\mathbb{Q}$ as the Easton support iteration which adds a non-reflecting stationary set of ordinals of cofinality η to each N -measurable limit of N -strong cardinals in the interval $(\kappa, k_2(\kappa)]$ implies that $N[G_0] \models \text{“}\mathbb{Q} \text{ is } \prec\kappa^+\text{-strategically closed”}$.

Since the standard arguments show that forcing with the κ -c.c. partial ordering $\mathbb{P}$ preserves that $N[G_0]$ remains κ -closed with respect to either $M[G_0]$ or $V[G_0]$, we know that $\mathbb{Q}$ is $\prec\kappa^+$ -strategically closed in both $M[G_0]$ and $V[G_0]$. We now construct G_1 in either $M[G_0]$ or $V[G_0]$ as follows. Fix a winning strategy for player II in the game of length κ^+ for the partial ordering $\mathbb{Q}$ and use it to construct a play $\langle q_\alpha : \alpha < \kappa^+ \rangle$ of the game. Since player II's moves are determined by her strategy, we need only specify the moves of the first player: if player II has just played the condition $q_{2\alpha}$ at the (even) stage 2α , let us direct player I to select and then play a condition $q_{2\alpha+1}$ above $q_{2\alpha}$ from the dense set D_α . Since the strategy plays at limit stages, this completes the construction of the play $\langle q_\alpha : \alpha < \kappa^+ \rangle$. Let $G_1 = \{p \in \mathbb{Q} : \exists \alpha < \kappa^+ (q_\alpha \geq p)\}$ be the filter generated by this increasing sequence of conditions. By construction, this filter meets all the dense sets D_α , and so it is $N[G_0]$ -generic over $\mathbb{Q}$.

It remains to construct in $V[G_0]$ the desired $N[G_0][G_1]$ -generic object G_2 over $\mathbb{R}$. To do this, we first observe that as $M \models \text{"}\kappa \text{ is a measurable limit of strong cardinals"}$, we can factor $k_1(\mathbb{P})$ as $\mathbb{P} * \dot{\mathbb{S}} * \dot{\mathbb{T}}$, where $\Vdash_{\mathbb{P}} \text{"}\dot{\mathbb{S}} = \dot{\mathbb{P}}_{\eta, \kappa}\text{"}$, and $\dot{\mathbb{T}}$ is a term for the rest of $k_1(\mathbb{P})$.

Note now that as in Lemma 2.4 of [9], $M \models \text{"No cardinal } \delta \in (\kappa, \lambda] \text{ is strong"}$. Thus, the field of $\dot{\mathbb{T}}$ is composed of all M -measurable limits of M -strong cardinals in the interval $(\lambda, k_1(\kappa))$, which implies that in M , $\Vdash_{\mathbb{P} * \dot{\mathbb{S}}} \text{"}\dot{\mathbb{T}} \text{ is } \prec\lambda^+\text{-strategically closed"}$. Further, since λ is a singular strong limit cardinal of cofinality at least κ , $|\lambda|^{<\kappa} = \lambda$. By Solovay's theorem [28] that GCH must hold at any singular strong limit cardinal above a strongly compact cardinal, we know that $2^\lambda = \lambda^+$. Therefore, as k_1 can be assumed to be generated by an ultrafilter over $P_\kappa(\lambda)$, we may calculate $|2^{k_1(\kappa)}|^M = |k_1(2^\kappa)| = |k_1(\kappa^+)| = |\{f : f : P_\kappa(\lambda) \rightarrow \kappa^+ \text{ is a function}\}| = |[\kappa^+]^\lambda| = \lambda^+$.

Work until otherwise specified in M . Consider the "term forcing" partial ordering $\mathbb{T}^*$ (see [15] for the first published account of term forcing or [14], Section 1.2.5, page 8; the notion is originally due to Laver) associated with $\dot{\mathbb{T}}$, i.e., $\tau \in \mathbb{T}^*$ essentially iff τ is a term in the forcing language with respect to $\mathbb{P} * \dot{\mathbb{S}}$ and $\Vdash_{\mathbb{P} * \dot{\mathbb{S}}} \text{"}\tau \in \dot{\mathbb{T}}\text{"}$, ordered by $\tau \geq \sigma$ iff $\Vdash_{\mathbb{P} * \dot{\mathbb{S}}} \text{"}\tau \geq \sigma\text{"}$. Since this definition, taken literally, would produce a proper class, we restrict the terms appearing in it to a sufficiently large set-sized collection (so that any term τ forced by the trivial condition to be in $\dot{\mathbb{T}}$ will be forced

by the trivial condition to be equal to an element of $\mathbb{T}^*$ of size $k_1(\kappa)$ in M .⁴ Since $\Vdash_{\mathbb{P}*\dot{\mathbb{S}}} \dot{\mathbb{T}}$ is $\prec\lambda^+$ -strategically closed, it can easily be verified that $\mathbb{T}^*$ is also $\prec\lambda^+$ -strategically closed in M and, since $M^\lambda \subseteq M$, in V as well.

Since $M \models "2^{k_1(\kappa)} = (k_1(\kappa))^+ = k_1(\kappa^+)"$, we can let $\langle D_\alpha : \alpha < \lambda^+ \rangle$ be an enumeration in V of the dense open subsets of $\mathbb{T}^*$ found in M and argue as we did when constructing G_1 to build in V an M -generic object H_2 over $\mathbb{T}^*$. As readers can verify for themselves, this line of reasoning remains valid, in spite of the fact λ is singular.

Note now that since N is an ultrapower of M via a normal ultrafilter $\mathcal{U} \in M$ over κ , Fact 2 of Section 1.2.2 of [14] tells us that $k_2''H_2$ generates an N -generic object G_2^* over $k_2(\mathbb{T}^*)$. By elementariness, $k_2(\mathbb{T}^*)$ is the term forcing in N defined with respect to $k_2(k_1(\mathbb{P}_\kappa)_{\kappa+1}) = \mathbb{P} * \dot{\mathbb{Q}}$. Therefore, since $j(\mathbb{P}) = k_2(k_1(\mathbb{P})) = \mathbb{P} * \dot{\mathbb{Q}} * \dot{\mathbb{R}}$, G_2^* is N -generic over $k_2(\mathbb{T}^*)$, and $G_0 * G_1$ is N -generic over $k_2(\mathbb{P} * \dot{\mathbb{S}})$, we know by Fact 1 of Section 1.2.5 of [14] (see also [15]) that $G_2 = \{i_{G_0 * G_1}(\tau) : \tau \in G_2^*\}$ is $N[G_0][G_1]$ -generic over $\mathbb{R}$. Thus, in $V[G_0]$, the embedding $j : V \rightarrow N$ lifts to $j : V[G_0] \rightarrow N[G_0][G_1][G_2]$. This means that $V[G_0] \models "\kappa \text{ is } \lambda \text{ strongly compact}"$. As λ was an arbitrary singular strong limit cardinal of cofinality at least κ , this completes the proof of Lemma 8.

□

We remark that the proof of Lemma 8 shows that a local version of this lemma is also possible. Specifically, if $V \models \text{"GCH} + \lambda \geq \kappa \text{ is a cardinal} + \kappa \text{ is a limit of strong cardinals} + \kappa \text{ is } \lambda \text{ supercompact}"$, then $V^\mathbb{P} \models "\kappa \text{ is } \lambda \text{ strongly compact}"$.

Lemma 9 $V^\mathbb{P} \models "\kappa \text{ has trivial Mitchell rank}"$.

⁴In the official definition of $\mathbb{T}^*$, the basic idea is to include only the canonical terms. Since $\dot{\mathbb{T}}$ is forced to have cardinality $k_1(\kappa)$, there is a set $\{\tau_\alpha : \alpha < k_1(\kappa)\}$ of terms such that for any other term τ , if $\Vdash_{\mathbb{P}*\dot{\mathbb{S}}} "\tau \in \dot{\mathbb{T}}"$, then there is a dense set of conditions in $\mathbb{P} * \dot{\mathbb{S}}$ forcing $"\tau = \tau_\alpha"$ for various α . While this collection of terms may not itself be adequate, we enlarge it as follows: for each maximal antichain $A \subseteq \mathbb{P} * \dot{\mathbb{S}}$ and each function $s : A \rightarrow \{\tau_\alpha : \alpha < k_1(\kappa)\}$, there is (by the Mixing Lemma of elementary forcing) a term τ_s such that $p \Vdash "\tau_\alpha = \tau_{s(p)}"$ for each $p \in A$; let $\mathbb{T}^*$ be the collection of all such terms τ_s , ranging over all maximal antichains of $\mathbb{P} * \dot{\mathbb{S}}$. Since $\mathbb{P} * \dot{\mathbb{S}}$ has size less than $k_1(\kappa)$ in M , the number of such terms is $k_1(\kappa)$. And finally, if a term τ is forced to be in $\dot{\mathbb{T}}$, then elementary forcing arguments establish that τ is forced to be equal to τ_s for some s .

Proof: Let G be V -generic over $\mathbb{P}$. If $V[G] \models “\kappa$ does not have trivial Mitchell rank”, then let $j : V[G] \rightarrow M[j(G)]$ be an embedding generated by a normal measure over κ in $V[G]$ witnessing this fact. In the terminology of [17], [18], and [19], $\mathbb{P}$ admits a gap below κ , and so by the Gap Forcing Theorem of [18] and [19], j must lift an embedding $j : V \rightarrow M$ that is definable in V . Since $j(\mathbb{P})$ also admits a gap below κ in M and κ is measurable in $M[j(G)]$, we similarly conclude that κ is measurable in M . Therefore, since κ is a limit of strong cardinals (we have already noted that any supercompact cardinal is a limit of strong cardinals), it follows that κ is in the field of $j(\mathbb{P})$. Thus, there is nontrivial forcing at stage κ , and so $j(G) = G * S * H$, where S is a non-reflecting stationary set of ordinals added by forcing over $M[G]$ with $(\mathbb{P}_{\eta,\kappa})^{M[G]}$ at stage κ and H is $M[G][S]$ -generic for the rest of the forcing $j(\mathbb{P})$. Since $V_{\kappa+1} \subseteq M \subseteq V$, it follows that $V_{\kappa+1}^{V[G]} = V_{\kappa+1}^{M[G]}$. From this it follows that $(\mathbb{P}_{\eta,\kappa})^{M[G]} = (\mathbb{P}_{\eta,\kappa})^{V[G]}$, and the dense open subsets of what we can now unambiguously write as $\mathbb{P}_{\eta,\kappa}$ are the same in both $M[G]$ and $V[G]$. Thus, the set S , which is an element of $V[G]$, is $V[G]$ -generic over $\mathbb{P}_{\eta,\kappa}$, a contradiction. This proves Lemma 9. $\square$

Lemma 10 $V^{\mathbb{P}} \models “No cardinal $\gamma \in (\eta, \kappa)$ is strongly compact”.$

Proof: By the definition of $\mathbb{P}$, $V^{\mathbb{P}} \models “Unboundedly many cardinals $\gamma \in (\eta, \kappa)$ contain non-reflecting stationary sets of ordinals of cofinality η ”.$

Therefore, by Theorem 4.8 of [29] and the succeeding remarks, $V^{\mathbb{P}} \models “No cardinal $\gamma \in (\eta, \kappa)$ is strongly compact”.$

This proves Lemma 10. $\square$

The proofs of Lemmas 8 - 10 complete the proof of Proposition 6. $\square$

We turn now to the proof of Proposition 7.

Proof: Let $V \models “ZFC + \kappa$ is supercompact”, with $\eta < \kappa$ fixed but arbitrary. As in the proof of Proposition 6, we can assume without loss of generality that $V \models “2^\kappa = \kappa^+”$ and that if necessary, this has been forced by the use of an η -directed closed partial ordering having cardinality 2^κ that

preserves all supercompact cardinals above η and creates no new supercompact or measurable cardinals above η . The proof of Proposition 7 is then given by the following two lemmas.

Lemma 11 *There is an η -directed closed partial ordering $\mathbb{P}$, preserving all supercompact cardinals above η except for κ , so that $V^{\mathbb{P}} \models$ “ κ is a non-supercompact strongly compact cardinal which contains a club disjoint from the measurable cardinals”. Furthermore, every strongly compact cardinal in $V^{\mathbb{P}}$ in the interval $(\eta, \kappa]$ is either supercompact in V or a measurable limit of supercompact cardinals in V .*

Proof: This proof follows the main idea of [20, Corollary 4.3], suitably modified so as to ensure the requirement concerning strongly compact cardinals in the extension. Let f be a uniform Laver function for all supercompact cardinals in the interval $(\eta, \kappa]$ (the existence of such a function is shown in [23] and [2]). The forcing $\mathbb{P}^0$ will be a kind of modified lottery preparation with respect to f . Specifically, $\mathbb{P}^0$ is the Easton support iteration of length κ which begins by adding a Cohen subset to η^+ . $\mathbb{P}^0$ then has nontrivial forcing at stage α only when $\alpha > \eta$ is a measurable cardinal, $\alpha \in \text{dom}(f)$, $f(\alpha)$ is an ordinal, $\alpha \leq f(\alpha)$ and $f''\alpha \subseteq V_\alpha$. At such stages, the forcing is the lottery sum in $V^{\mathbb{P}^\alpha}$ of all partial orderings in $H(f(\alpha)^+)$ having β -directed closed dense subsets for every $\beta < \alpha$. After the lottery sum forcing, we perform the forcing to add a non-reflecting stationary subset to the next inaccessible cardinal above $f(\alpha)$, consisting of ordinals of cofinality $\max(\eta^+, \beta_\alpha^+)$, where β_α is the supremum of the supercompact cardinals of V below α . (Note: this will prevent any cardinals in the interval $(\max(\eta, \beta_\alpha), f(\alpha)]$ from becoming strongly compact in the extension.) We may assume that $\text{dom}(f)$ contains no supercompact cardinals, so that the forcing at any supercompact cardinal stage is trivial.

Let us argue that forcing with $\mathbb{P}^0$ preserves all supercompact cardinals δ of V in the interval $(\eta, \kappa]$. For this, it will suffice for us to argue that δ is supercompact in $V^{\mathbb{P}^\delta}$ and indestructible there by any further δ -directed closed forcing. This suffices because there is no forcing right at stage δ (as it is not in the domain of f), and the subsequent forcing from stage δ up to κ has a δ -directed closed dense subset. Following [20, Corollary 4.6], fix any δ -directed closed forcing $\mathbb{Q} \in V^{\mathbb{P}^\delta}$ and any $\lambda \geq \delta$. Choose $\theta > (\max(2^{\lambda^{<\delta}}, |\text{TC}(\dot{\mathbb{Q}}|)))^+$. Since f is a Laver function, there is a

θ supercompactness embedding $j : V \rightarrow M$ with critical point δ and $j(f)(\delta) = \theta$. Let $G_\delta * g \subseteq \mathbb{P}_\delta * \dot{\mathbb{Q}}$ be V -generic. Since $\dot{\mathbb{Q}}$ is allowed in the stage δ lottery of $j(\mathbb{P}_\delta)$, we may work above the condition opting for this partial ordering, and factor the forcing as $j(\mathbb{P}_\delta) = \mathbb{P}_\delta * \dot{\mathbb{Q}} * \dot{\mathbb{P}}_\delta^{j(\delta)}$, where $\dot{\mathbb{P}}_\delta^{j(\delta)}$ is a term for the rest of the forcing from stages δ up to $j(\delta)$, starting with the non-reflecting stationary set forcing at stage δ . Force to add $G_\delta^{j(\delta)} \subseteq \mathbb{P}_\delta^{j(\delta)}$, and lift the embedding to $j : V[G_\delta] \rightarrow M[j(G_\delta)]$ in $V[G_\delta][g][G_\delta^{j(\delta)}]$, where $j(G_\delta) = G_\delta * g * G_\delta^{j(\delta)}$. Using a master condition above $j''g$, similarly force to add $j(g) \subseteq j(\dot{\mathbb{Q}})$, and lift the embedding to $j : V[G_\delta][g] \rightarrow M[j(G_\delta)][j(g)]$ in $V[G_\delta][g][G_\delta^{j(\delta)}][j(g)]$. The point is now that the induced λ supercompactness measure μ , defined by $X \in \mu$ iff $j''\lambda \in j(X)$, has size $2^{\lambda^{<\delta}}$, and therefore μ could not have been added by the extra forcing $\mathbb{P}_\delta^{j(\delta)} * j(\dot{\mathbb{Q}})$, since that forcing is $2^{\lambda^{<\delta}}$ -strategically closed. Hence, the measure μ must be in $V[G_\delta][g]$, and so δ is λ supercompact there, as desired. So every supercompact cardinal of V in the interval $(\eta, \kappa]$ is preserved to $V^{\mathbb{P}^0}$ and becomes indestructible there.

Now let $\mathbb{C}_\kappa$ be the partial ordering defined in $V^{\mathbb{P}^0}$ which adds a club of non-measurable cardinals to κ above η , i.e., $\mathbb{C}_\kappa = \{c : c \text{ is a closed, bounded subset of } \kappa \text{ containing no cardinals that are measurable in } V^{\mathbb{P}^0} \text{ and } \eta < \sup(c)\}$, ordered by end-extension. Let $\mathbb{P} = \mathbb{P}^0 * \dot{\mathbb{C}}_\kappa$. For every $\delta < \kappa$, the set of elements of $\mathbb{C}_\kappa$ which mention an element above δ is a δ^+ -directed closed dense open subset of $\mathbb{C}_\kappa$. This can be seen by taking the union of a δ -chain of these sorts of conditions and adding the supremum (which cannot be measurable because it is not regular). Thus, the measurable cardinals below κ in $V^{\mathbb{P}^0}$ and $V^{\mathbb{P}^0 * \dot{\mathbb{C}}_\kappa} = V^\mathbb{P}$ are the same. Also, $\mathbb{P}$ is η -directed closed, and for any V -supercompact cardinal $\delta \in (\eta, \kappa]$, by indestructibility, $V^{\mathbb{P}^0 * \dot{\mathbb{C}}_\kappa} = V^\mathbb{P} \models \text{"}\delta \text{ is a supercompact cardinal whose supercompactness is indestructible under } \delta\text{-directed closed forcing"}$. In addition, since by its definition, $|\mathbb{P}| = \kappa$, the results of [25] imply that forcing with $\mathbb{P}$ preserves all supercompact cardinals above κ , and $V^\mathbb{P} \models \text{"}2^\kappa = \kappa^+\text{"}$.

Since f is a Laver function for κ , we know that for any cardinal $\lambda \geq \kappa$, there is a supercompact ultrafilter $\mathcal{U}_0$ over $P_\kappa(\lambda)$ so that for $j_0 : V \rightarrow M$ the associated elementary embedding generated by $\mathcal{U}_0$, $j_0(f)(\kappa) = \lambda$. As $M \models \text{"}([\text{id}]_{\mathcal{U}_0})^M = \langle j_0(\alpha) : \alpha < \lambda \rangle\text{"}$, it follows that $M \models \text{"}|\text{[id]}_{\mathcal{U}_0}|^M = \lambda\text{"}$. Therefore, $M \models \text{"}j_0(f)(\kappa) \geq |\text{[id]}_{\mathcal{U}_0}|^M\text{"}$. Further, if $\lambda \geq 2^\kappa$, as in the proof of Lemma 8, we can find

$j_1 : M \rightarrow N$ an elementary embedding generated by a normal ultrafilter $\mathcal{U}_1 \in M$ of trivial Mitchell rank so that $N \models “\kappa$ isn’t measurable”.

Let $\mathcal{U}$ be the κ -additive, fine measure over $P_\kappa(\lambda)$ defined by $x \in \mathcal{U}$ iff $j_1(\langle j_0(\alpha) : \alpha < \lambda \rangle) \in x$, with the associated elementary embedding $j : V \rightarrow M^*$. Thus, $\kappa \in j(\{\delta < \kappa : \delta \text{ isn't measurable}\})$ and $j(f)(\kappa) \geq |[\text{id}]_{\mathcal{U}}|^{M^*}$. We are therefore in a position to apply the argument of [20, Theorem 4.2] to conclude that $V^{\mathbb{P}^{0*}\dot{C}_\kappa} = V^{\mathbb{P}} \models “\kappa$ is strongly compact”.

And we’ve explicitly added a club of non-measurable cardinals to κ .

It remains to check that every strongly compact cardinal of $V^{\mathbb{P}}$ in the interval $(\eta, \kappa]$ is either supercompact in V or a measurable limit of supercompact cardinals in V . Note that by construction, whenever $\gamma \in (\eta, \kappa]$ is a supercompact cardinal of V which isn’t a limit of supercompact cardinals, then for unboundedly many λ between $\max(\eta, \beta_\gamma)$ and γ , we have added a non-reflecting stationary subset to λ consisting of ordinals of cofinality $\max(\eta^+, \beta_\gamma^+)$. This necessarily destroys all strongly compact cardinals between $\max(\eta, \beta_\gamma)$ and γ . So no strongly compact cardinals in the extension in the interval $(\eta, \kappa]$ lie between the supercompact cardinals of V in the interval $(\eta, \kappa]$. Since furthermore by the Gap Forcing Theorem of [18] and [19], no new measurable or supercompact cardinals were created, we conclude that every strongly compact cardinal in the extension is either supercompact in V or a measurable limit of supercompact cardinals in V , as we claimed. This completes the proof of Lemma 11.

□

Lemma 12 *There is an η -directed closed partial ordering $\mathbb{P}$, preserving all supercompact cardinals above η except for κ , so that $V^{\mathbb{P}} \models “\kappa$ is a non-supercompact strongly compact strong cardinal”. Furthermore, every strongly compact cardinal in $V^{\mathbb{P}}$ in the interval $(\eta, \kappa]$ is either supercompact in V or a measurable limit of supercompact cardinals in V .*

Proof: Let $\mathbb{P}$ be the Easton support iteration of length κ which begins by adding a Cohen subset to η^+ . $\mathbb{P}$ then has nontrivial forcing only at those stages $\alpha > \eta$ which are strong cardinal limits of strong cardinals. At such a stage α , we force with the lottery sum of all α -directed closed partial orderings having rank below the least strong cardinal δ above α , which add a Cohen subset to

α . We next perform the forcing to add a non-reflecting stationary subset of ordinals of cofinality $\max(\eta^+, \beta_\alpha^+)$ to δ , where β_α is as in Lemma 11. It follows easily that $\mathbb{P}$ is η -directed closed.

For any $\lambda > \kappa$ so that $\lambda = \beth_\lambda$, we can choose $j : V \rightarrow M$ to be an elementary embedding witnessing the λ strongness of κ so that $M \models \text{“}\kappa \text{ isn't } \lambda \text{ strong”}$. This means that by the definition of $\mathbb{P}$, no forcing is done in M at stage κ . Therefore, the standard lifting argument for strongness embeddings will show that κ remains strong in $V^\mathbb{P}$.⁵ Further, if now $\lambda \geq 2^\kappa$ and $j : V \rightarrow M$ is an elementary embedding witnessing the λ supercompactness of κ , then by remarks made in the proof of Lemma 8, κ is a strong cardinal limit of strong cardinals in both V and M . This means that in M , the forcing for adding a Cohen subset to κ is part of the lottery sum found at stage κ in the definition of $j(\mathbb{P})$. Hence, since we are able to opt for this forcing at stage κ in M , we can apply the argument given in the proof of Lemma 8 to show that $V^\mathbb{P} \models \text{“}\kappa \text{ is strongly compact”}$. In addition, we can modify the proof of Lemma 9 by replacing the embedding j with an embedding that is alleged to witness the fact that κ is 2^κ supercompact in the generic extension and by replacing the non-reflecting stationary set of ordinals of Lemma 9 with a Cohen subset of κ . This last change is possible since the stage κ forcing in M must add a Cohen subset to κ . The proof of Lemma 9 now goes through in an analogous manner as earlier to show that after forcing with $\mathbb{P}$, κ isn't 2^κ supercompact. Therefore, since $|\mathbb{P}| = \kappa$, we know $V^\mathbb{P} \models \text{“}2^\kappa = \kappa^+\text{”}$, and the results of [25] once again show that forcing with $\mathbb{P}$ preserves all supercompact cardinals above κ .

Since the proof that every strongly compact cardinal in $V^\mathbb{P}$ in the interval $(\eta, \kappa]$ is either supercompact in V or a measurable limit of supercompact cardinals in V is exactly as given in the proof of Lemma 11, we complete the proof of Lemma 12 by showing that $\mathbb{P}$ preserves all supercompact cardinals in the interval (η, κ) . To see this, let $\delta \in (\eta, \kappa)$ be supercompact. Let $\lambda > \kappa$ be a singular strong limit cardinal of cofinality δ (so the GCH holds at λ). Choose $j : V \rightarrow M$ an elementary embedding witnessing the λ supercompactness of δ so that $M \models \text{“}\delta \text{ isn't } \lambda \text{ supercompact”}$. Since δ is a strong cardinal limit of strong cardinals, δ is a stage in the definition

⁵One factors through by the normal measure, constructs a generic over the normal measure ultrapower, and pushes this generic up to the strongness ultrapower. See, for example, Lemma 2.5 of [9]. A key part of the argument is that as in Lemma 2.5 of [9], since no cardinal $\delta \in [\kappa, \lambda]$ in the strongness ultrapower is strong, the first stage of nontrivial forcing in the strongness ultrapower takes place well after stage λ .

of $\mathbb{P}$ at which a nontrivial forcing is done, i.e., if we write $\mathbb{P} = \mathbb{P}_\delta * \dot{\mathbb{P}}^\delta$, $\dot{\mathbb{P}}^\delta$ will be a term for a partial ordering that is δ -directed closed and adds a Cohen subset to δ . Because δ is $<\lambda$ supercompact but not λ supercompact in M , it follows as before that $M \models$ “There are no strong cardinals in the interval $(\delta, \lambda]$ ”. This means that $\mathbb{P}^\delta$ is an allowable choice in the stage δ lottery in $M^{\mathbb{P}_\delta}$, and any further nontrivial forcing in M takes place well after stage λ . Therefore, if G_0 is V -generic over $\mathbb{P}_\delta$ and G_1 is $V[G_0]$ -generic over $\mathbb{P}^\delta$, in $V[G_0][G_1]$, standard arguments show that j lifts to $j : V[G_0][G_1] \rightarrow M[G_0][G_1][G_2][G_3]$, where G_2 and G_3 are suitably generic objects constructed in $V[G_0][G_1]$, and G_3 contains a master condition for G_1 . We can thus infer that $V^\mathbb{P} \models$ “ δ is λ supercompact”. Since λ can be chosen to be arbitrarily large, this completes the proof of Lemma 12.

□

Lemmas 11 and 12 complete the proof of Proposition 7.

□

We conclude Section 2 by remarking that it is possible to modify the definition of $\mathbb{P}$ given in the proofs of Propositions 6 and 7 so that after forcing with $\mathbb{P}$, κ retains a nontrivial degree of supercompactness. To do this, $\mathbb{P}$ is first altered so as initially to force $2^\kappa = \kappa^+$ and $2^{\kappa^+} = \kappa^{++}$ if necessary via an η -directed closed partial ordering that preserves all V -supercompact cardinals, while admitting a gap below the least inaccessible above η . The forcing $\mathbb{P}$ is then defined as in the proof of Proposition 6 and Lemma 12, except that nontrivial forcing is done only at stages α which are α^+ supercompact and are a limit of strong cardinals in the partial ordering which is the analogue of the one defined in Proposition 6, or at stages α which are α^+ supercompact and are strong cardinal limits of strong cardinals in the partial ordering which is the analogue of the one defined in Lemma 12. If j in the proof of Lemma 9 is chosen as a κ^+ supercompactness embedding witnessing that κ has nontrivial Mitchell rank with respect to κ^+ supercompactness (meaning that there is a κ^+ supercompactness embedding $j : V \rightarrow M$ with $M \models$ “ κ is κ^+ supercompact”) instead of an embedding witnessing that κ has nontrivial Mitchell rank and the word “measurable” is replaced by the phrase “ κ^+ supercompact”, then the remainder of the proof of Lemma 9 suitably

modified shows that $V^{\mathbb{P}} \models “\kappa \text{ has trivial Mitchell rank with respect to } \kappa^+ \text{ supercompactness}”$. By replacing the embedding k_2 in Lemma 8 with a κ^+ supercompactness embedding so that $M \models “\kappa \text{ isn't } \kappa^+ \text{ supercompact}”$, the proof of Lemma 8 also goes through with slight modifications and shows that $V^{\mathbb{P}} \models “\kappa \text{ is both strongly compact and } \kappa^+ \text{ supercompact}”$. The proof that all V -supercompact cardinals above η except for κ remain supercompact is virtually identical to the one given in Lemma 12 in the appropriate analogue of Lemma 12, and the proofs that there are no strongly compact cardinals in the interval (η, κ) in the appropriate analogue of Lemma 10 or that the strongly compact cardinals in $V^{\mathbb{P}}$ in the interval $(\eta, \kappa]$ are either supercompact in V or measurable limits of supercompact cardinals in V in the appropriate analogue of Lemma 12 are identical to the ones given in the proofs of these lemmas. Thus, by modifying the definition of $\mathbb{P}$, it is possible to produce an η -directed closed partial ordering $\mathbb{P}$ with the same properties as in Propositions 6 and 7 except that in $V^{\mathbb{P}}$, κ is a non-supercompact strongly compact κ^+ supercompact cardinal having trivial Mitchell rank with respect to κ^+ supercompactness (see also pages 113–114 of [6]). Further modifications allow $V^{\mathbb{P}}$ to witness even larger degrees of supercompactness for κ , while remaining strongly compact and not supercompact. One can also arrange that in $V^{\mathbb{P}}$ the cardinal κ has trivial Mitchell rank with respect to its degree of supercompactness.

3 The Proof of the Main Theorem

We turn now to the proof of our Main Theorem, Theorem 2.

Proof: Let $V_0 \models “\text{ZFC} + \mathcal{K} \text{ is the class of supercompact cardinals} + \mathcal{A} \subseteq \mathcal{K} \text{ and } \mathcal{A} \text{ contains none of its limit points.}”$ By initially forcing with an Easton support iteration $\mathbb{P}^*$ that first adds a Cohen subset to ω , next forces GCH if necessary at all measurable cardinals κ by adding a Cohen subset to κ^+ (which preserves all supercompact cardinals and creates no new supercompact or measurable cardinals) and then is followed by a modified version of the partial ordering used in the proof of Theorem 1 of [2], we may assume that $V = V_0^{\mathbb{P}^*} \models “\text{ZFC} + \mathcal{K} \text{ is the class of supercompact cardinals} + 2^\kappa = \kappa^+ \text{ if } \kappa \text{ is supercompact} + \text{Every supercompact cardinal } \kappa \text{ is Laver indestructible [24] under } \kappa^+ \text{-directed closed forcing} + \text{The strongly compact and supercompact cardinals coincide precisely,}”$

except possibly at measurable limit points”. The modification is to allow only δ^+ -directed closed partial orderings in the indestructibility forcing at stage δ . In addition to forcing the previous properties, this modification will ensure that all measurable limits of supercompact cardinals at which GCH holds in V_0 are preserved and continue to satisfy GCH in V .⁶

We now define the forcing $\mathbb{P}$ that will accomplish our goals. Work in V . For each $\kappa \in \mathcal{A}$, let $\delta_\kappa = 2^{\sup(\mathcal{A} \cap \kappa)}$, with $\delta_{\kappa_0} = \aleph_2$ for κ_0 the least element of $\mathcal{A}$. Since $\mathcal{A}$ contains none of its limit points, it follows that $\delta_\kappa < \kappa$. For each $\kappa \in \mathcal{A}$, let $\mathbb{P}_\kappa$ be the partial ordering which forces κ to be a non-supercompact strongly compact cardinal by first taking $\eta = \delta_\kappa$ and then using any of the $\eta = \delta_\kappa$ -directed closed partial orderings given in Proposition 7. Let $\mathbb{P}$ be the Easton support product $\prod_{\kappa \in \mathcal{A}} \mathbb{P}_\kappa$. Please note that this is a product, not an iteration. The field of $\mathbb{P}_\kappa$ lies in the interval (δ_κ, κ) , which contains no elements of $\mathcal{A}$, and so the fields of the partial orderings $\mathbb{P}_\kappa$ occur in disjoint blocks. Although this may be class forcing, the standard Easton arguments show $V^\mathbb{P} \models \text{ZFC}$.

Lemma 13 *If $\kappa \in \mathcal{K} - \mathcal{A}$, then $V^\mathbb{P} \models “\kappa \text{ is supercompact}”$.*

Proof: Suppose that $\kappa \in \mathcal{K} - \mathcal{A}$. Let η be the least element of $\mathcal{A}$ above κ , and factor the forcing in V as $\mathbb{P} = \mathbb{Q}^\eta \times \mathbb{P}_\eta \times \mathbb{Q}_{<\eta}$, where $\mathbb{Q}^\eta = \prod_{\beta > \eta, \beta \in \mathcal{A}} \mathbb{P}_\beta$ and $\mathbb{Q}_{<\eta} = \prod_{\beta < \eta, \beta \in \mathcal{A}} \mathbb{P}_\beta$. Please observe that $\mathbb{Q}^\eta$ is η^+ -directed closed.

Suppose that κ is not a limit point of $\mathcal{A}$. It follows that $\mathcal{A}$ is bounded below κ and so $\delta_\eta < \kappa$ and $|\mathbb{Q}_{<\eta}| < \kappa$. Since κ ’s supercompactness is indestructible in V and $\mathbb{Q}^\eta$ is η^+ -directed closed, we know that κ is supercompact in $V^{\mathbb{Q}^\eta}$.

⁶Let us outline the proof that $\mathbb{P}^*$ accomplishes this. The portion of $\mathbb{P}^*$ that forces GCH at a V_0 -measurable cardinal κ is an iteration that can be factored as $\mathbb{Q}_0 * \dot{\mathbb{Q}}_1$, where the field of $\mathbb{Q}_0$ is composed of ordinals below κ . If κ is any measurable cardinal at which GCH holds, then by choosing $j : V \rightarrow M$ as an elementary embedding witnessing κ ’s measurability so that $M \models “\kappa \text{ isn’t measurable}”$, we can show via a standard lifting argument (such as given in the proof of Theorem 3.5 of [20]) that j lifts to an elementary embedding witnessing κ ’s measurability after forcing with $\mathbb{Q}_0$. Since $\Vdash_{\mathbb{Q}_0} “\dot{\mathbb{Q}}_1 \text{ is } \kappa^+\text{-directed closed}”$, κ remains measurable after forcing with $\mathbb{Q}_1$. Further, since $|\mathbb{Q}_0| \leq \kappa$, GCH at κ is preserved after forcing with $\mathbb{Q}_0 * \dot{\mathbb{Q}}_1$. Then, since the remainder of $\mathbb{P}^*$ is a Laver style iteration for forcing indestructibility which at each nontrivial stage δ does a forcing which is δ^+ -directed closed, it can be factored as $\mathbb{Q}_2 * \dot{\mathbb{Q}}_3$, where for κ a V_0 -measurable limit of supercompact cardinals, the field of $\mathbb{Q}_2$ is composed of ordinals below κ , $|\mathbb{Q}_2| \leq \kappa$ and $\Vdash_{\mathbb{Q}_2} “\dot{\mathbb{Q}}_3 \text{ is } \kappa^+\text{-directed closed}”$. The argument that forcing with $\mathbb{Q}_0 * \dot{\mathbb{Q}}_1$ preserves both κ ’s measurability and GCH at κ can now be applied to $\mathbb{Q}_2 * \dot{\mathbb{Q}}_3$. Standard arguments for the preservation of supercompactness under Easton support iterations show that any supercompact cardinal is preserved after forcing with $\mathbb{Q}_0 * \dot{\mathbb{Q}}_1$, and the arguments of [2] show that the remaining claimed properties of $\mathbb{P}^* = \mathbb{Q}_0 * \dot{\mathbb{Q}}_1 * \dot{\mathbb{Q}}_2 * \dot{\mathbb{Q}}_3$ hold. The Gap Forcing Theorem of [18] and [19] then shows that $\mathcal{K}$ is precisely the class of supercompact cardinals in V .

We claim that the strong cardinals below η are the same in $V^{\mathbb{Q}^\eta}$ as in V . To see this, observe first that η is supercompact and therefore strong in both V and, by indestructibility, in $V^{\mathbb{Q}^\eta}$. Therefore, a cardinal $\delta < \eta$ is strong in either V or $V^{\mathbb{Q}^\eta}$ iff it is σ strong for every $\sigma < \eta$, since by the second paragraph of Lemma 2.1 of [9], if α is β strong for every $\beta < \gamma$ and γ is strong, then α is strong. But since $\mathbb{Q}^\eta$ is η^+ -directed closed, it neither creates nor destroys any extenders below η , and so the two models agree on strongness below η .

In addition, since the models agree up to η , the construction of a universal Laver function for the supercompact cardinals in the interval $(\delta_\eta, \eta]$ is the same in V or $V^{\mathbb{Q}^\eta}$. Therefore, the forcing $\mathbb{P}_\eta$ satisfies the same definition in either V or $V^{\mathbb{Q}^\eta}$, and so by applying Proposition 7 in $V^{\mathbb{Q}^\eta}$, since $\mathbb{P}_\eta$ preserves all supercompact cardinals in the interval (δ_η, η) , we conclude $V^{\mathbb{Q}^\eta \times \mathbb{P}_\eta} \models “\kappa$ is supercompact”. Finally, since $|\mathbb{Q}_{<\eta}| < \kappa$, we conclude by [25] that $V^\mathbb{P} = V^{\mathbb{Q}^\eta \times \mathbb{P}_\eta \times \mathbb{Q}_{<\eta}} \models “\kappa$ is supercompact”, as desired.

Assume next that $\kappa \in \mathcal{K} - \mathcal{A}$ and κ is a limit point of $\mathcal{A}$. In this case, $\delta_\eta = 2^\kappa$, and so the partial ordering $\mathbb{Q}^\eta \times \mathbb{P}_\eta$ is δ_η -directed closed. By indestructibility, therefore, κ is supercompact in the model $\overline{V} = V^{\mathbb{Q}^\eta \times \mathbb{P}_\eta}$. Furthermore, $V \models “|\mathbb{Q}_{<\eta}| = \kappa”$.

Choose any cardinal $\lambda > \kappa$ and let $\gamma = |2^{\lambda^{<\kappa}}|$. Take $j : \overline{V} \rightarrow M$ to be an elementary embedding witnessing the γ supercompactness of κ in $\overline{V}$ so that $M \models “\kappa$ isn’t γ supercompact”. It must then be the case, as in Lemma 8 and Lemma 2.4 of [9], that $M \models “\text{No cardinal } \delta \in (\kappa, \gamma] \text{ is strong}”$. Writing $j(\mathbb{Q}_{<\eta})$ as $\mathbb{Q}_{<\eta} \times \mathbb{Q}^*$, this means that the least ordinal in the field of $\mathbb{Q}^*$ is above γ . Thus, if G is $\overline{V}$ -generic over $\mathbb{Q}_{<\eta}$ and H is $\overline{V}[G]$ -generic over $\mathbb{Q}^*$, in $\overline{V}[G \times H]$, j lifts to $\bar{j} : \overline{V}[G] \rightarrow M[G \times H]$ via the definition $\bar{j}(i_G(\tau)) = i_{G \times H}(j(\tau))$. Since $M \models “\mathbb{Q}^*$ is γ -strategically closed” and $M^\gamma \subseteq M$, it follows that for any cardinal $\delta \leq \gamma$, the two models $\overline{V}[G]$ and $\overline{V}[G \times H] = \overline{V}[H \times G]$ contain the same subsets of δ . This means the supercompactness measure $\mathcal{U}$ over $(P_\kappa(\lambda))^{\overline{V}[G]}$ in $\overline{V}[G \times H]$ given by $x \in \mathcal{U}$ iff $\langle j(\beta) : \beta < \lambda \rangle \in \bar{j}(x)$ is in $\overline{V}[G]$. Hence, $V^\mathbb{P} = V^{\mathbb{Q}^\eta \times \mathbb{P}_\eta \times \mathbb{Q}_{<\eta}} \models “\kappa$ is supercompact”, as desired. This completes the proof of Lemma 13.

□

Lemma 14 *If $\kappa \in \mathcal{A}$, then $V^\mathbb{P} \models “\kappa$ is strongly compact but not supercompact + $2^\kappa = \kappa^+”$.*

Proof: In analogy with the above argument, we factor the forcing as $\mathbb{P} = \mathbb{Q}^\kappa \times \mathbb{P}_\kappa \times \mathbb{Q}_{<\kappa}$, where $\mathbb{Q}^\kappa = \prod_{\beta > \kappa, \beta \in \mathcal{A}} \mathbb{P}_\beta$, and $\mathbb{Q}_{<\kappa} = \prod_{\beta < \kappa, \beta \in \mathcal{A}} \mathbb{P}_\beta$. Since $\mathbb{Q}^\kappa$ is κ^+ -directed closed, we know once again by indestructibility that κ is supercompact in $V^{\mathbb{Q}^\kappa}$. We also know again that the strong cardinals below κ of V and $V^{\mathbb{Q}^\kappa}$ are the same and that the partial ordering $\mathbb{P}_\kappa$ of Proposition 7 is constructed in the same way in V as in $V^{\mathbb{Q}^\kappa}$. Therefore, by Proposition 7, we know that κ is a non-supercompact strongly compact cardinal in $V^{\mathbb{Q}^\kappa \times \mathbb{P}_\kappa}$ (and either has a club disjoint from the measurable cardinals or else remains a strong cardinal, depending on the version of $\mathbb{P}_\kappa$ selected). Finally, since our assumption on $\mathcal{A}$ guarantees that κ is not a limit point of $\mathcal{A}$, we know $|\mathbb{Q}_{<\kappa}| < \kappa$. By the results of [25] and [21], therefore, $V^{\mathbb{Q}^\kappa \times \mathbb{P}_\kappa \times \mathbb{Q}_{<\kappa}} = V^\mathbb{P} \models “\kappa \text{ is a non-supercompact strongly compact cardinal which either has a club disjoint from the measurables or is a strong cardinal}”$. Lastly, we observe that none of the three factors destroys $2^\kappa = \kappa^+$, so the proof of Lemma 14 is complete. $\square$

Lemma 15 *If $V \models “\kappa \text{ is a measurable limit of } \mathcal{A} + 2^\kappa = \kappa^+”$, then $V^\mathbb{P} \models “\kappa \text{ is a measurable limit of } \mathcal{A} + 2^\kappa = \kappa^+”$.*

Proof: Suppose that $V \models “\kappa \text{ is a measurable limit of } \mathcal{A} + 2^\kappa = \kappa^+”$. By hypothesis, we know that $\kappa \notin \mathcal{A}$. We may therefore factor the forcing $\mathbb{P}$ as $\mathbb{P} = \mathbb{Q}^\kappa \times \mathbb{Q}_{<\kappa}$, where $\mathbb{Q}^\kappa = \prod_{\beta > \kappa, \beta \in \mathcal{A}} \mathbb{P}_\beta$, and $\mathbb{Q}_{<\kappa} = \prod_{\beta < \kappa, \beta \in \mathcal{A}} \mathbb{P}_\beta$. Fix an elementary embedding $j : V \rightarrow M$ arising from a normal measure over κ , such that $M \models “\kappa \text{ isn't measurable}”$.

First, we observe that the forcing $\mathbb{Q}^\kappa$ is κ^+ -directed closed, and therefore cannot destroy the measurability of κ . So we need only prove that κ is measurable after forcing with $\mathbb{Q}_{<\kappa}$. Because κ is a limit point of $\mathcal{A}$, the forcing $j(\mathbb{Q}_{<\kappa})$ factors as $\mathbb{Q}_{<\kappa} \times \mathbb{Q}_{\kappa, j(\kappa)}$, where $\mathbb{Q}_{\kappa, j(\kappa)}$ is the product of the partial orderings $\mathbb{P}_\beta$ in M for $\beta \in j(\mathcal{A}) \cap [\kappa, j(\kappa))$. Since κ is not measurable in M , it is definitely not in $j(\mathcal{A})$, and so the first element of the field of $\mathbb{Q}_{\kappa, j(\kappa)}$ is strictly above κ . It follows that this forcing is κ^+ -directed closed in M , and so since $2^\kappa = \kappa^+$ in V , we may employ the usual diagonalization argument (see, e.g., the construction of the generic object G_1 in Lemma 8) to build in V an M -generic filter $G_{\kappa, j(\kappa)} \subseteq \mathbb{Q}_{\kappa, j(\kappa)}$. Putting this together with any V -generic $G_{<\kappa}$ for $\mathbb{Q}_{<\kappa}$,

we may lift the embedding to $j : V[G_{<\kappa}] \rightarrow M[j(G_{<\kappa})]$, where $j(G_{<\kappa}) = G_{<\kappa} \times G_{\kappa, j(\kappa)}$. This lifted embedding witnesses the measurability of κ in $V[G_{<\kappa}]$, as desired. Finally, since $\mathbb{Q}^\kappa$ is κ^+ -directed closed and $|\mathbb{Q}_{<\kappa}| \leq \kappa$, $V^{\mathbb{Q}^\kappa \times \mathbb{Q}_{<\kappa}} = V^\mathbb{P} \models "2^\kappa = \kappa^+"$. This proves Lemma 15. □

Lemma 16 *The strongly compact cardinals of $V^\mathbb{P}$ are precisely the cardinals of $\mathcal{K}$ and their measurable limit points, and these are all strongly compact in V and V_0 . In addition, the supercompact cardinals of $V^\mathbb{P}$ are all supercompact in V and V_0 as well.*

Proof: We have already proved that the cardinals of $\mathcal{K}$ remain strongly compact in $V^\mathbb{P}$, so suppose towards a contradiction that $V^\mathbb{P} \models "\delta \notin \mathcal{K}$ is strongly compact and isn't a measurable limit point of $\mathcal{K}"$. If $\mathcal{A}$ is bounded below δ , then $|\mathbb{P}| < \delta$, and so by the results of [25], δ is strongly compact in V , contrary to our assumption that the strongly compact cardinals of V are either in $\mathcal{K}$ or measurable limits of $\mathcal{K}$. So we may assume $\mathcal{A}$ is not bounded below δ . Since δ cannot be a limit point of $\mathcal{A}$, there is a least element κ in $\mathcal{A}$ above δ , and $\delta \in (\delta_\kappa, \kappa)$.

As in Lemma 13, factor $\mathbb{P}$ as $\mathbb{Q}^\kappa \times \mathbb{P}_\kappa \times \mathbb{Q}_{<\kappa}$. Once again, regardless of which version is chosen, $\mathbb{P}_\kappa$ is constructed the same in either V or $V^{\mathbb{Q}^\kappa}$, and has the properties identified in Proposition 7 in either model. We therefore know that in particular, since δ isn't in V either an element of $\mathcal{K}$ or a measurable limit of elements of $\mathcal{K}$, $V^{\mathbb{Q}^\kappa \times \mathbb{P}_\kappa} \models "\delta$ isn't strongly compact". Hence, once again, the results of [25] yield that $V^{\mathbb{Q}^\kappa \times \mathbb{P}_\kappa \times \mathbb{Q}_{<\kappa}} = V^\mathbb{P} \models "\delta$ isn't strongly compact", contradicting our assumption that $V^\mathbb{P} \models "\delta$ is strongly compact".

We complete the proof of Lemma 16 by showing that any measurable limit of $\mathcal{K}$ or supercompact cardinal in $V^\mathbb{P}$ has this feature also in both V and V_0 . We first verify that the forcing $\mathbb{P}$ creates no new measurable limits of $\mathcal{K}$. Suppose κ is a limit point of $\mathcal{K}$ that is not measurable in V . If κ is not a limit point of $\mathcal{A}$, let η be the least element of $\mathcal{A}$ above κ . As in Lemma 13, factor $\mathbb{P}$ as $\mathbb{Q}^\eta \times \mathbb{P}_\eta \times \mathbb{Q}_{<\eta}$. Note that $\kappa \in (\delta_\eta, \eta)$, and as in Lemma 13, $\mathbb{P}_\eta$ satisfies the same definition in either V or $V^{\mathbb{Q}^\eta}$. In particular, we know that $\mathbb{Q}^\eta$ is η^+ -directed closed, and $\mathbb{P}_\eta$ admits a gap in either V or $V^{\mathbb{Q}^\eta}$ below the least inaccessible above η . Putting these facts together, and using the Gap Forcing

Theorem of [18] and [19], we may therefore infer that $V^{\mathbb{Q}^\eta \times \mathbb{P}_\eta} \models \text{“}\kappa \text{ isn't measurable”}$. As $|\mathbb{Q}_{<\eta}| < \kappa$, the results of [25] then immediately tell us that $V^{\mathbb{Q}^\eta \times \mathbb{P}_\eta \times \mathbb{Q}_{<\eta}} = V^\mathbb{P} \models \text{“}\kappa \text{ isn't measurable”}$ as well.

Suppose now that κ is a limit point of $\mathcal{A}$. This allows us to factor the forcing as $\mathbb{P} = \mathbb{Q}^\kappa \times \mathbb{Q}_{<\kappa}$, where $\mathbb{Q}^\kappa = \prod_{\beta > \kappa, \beta \in \mathcal{A}} \mathbb{P}_\beta$, and $\mathbb{Q}_{<\kappa} = \prod_{\beta < \kappa, \beta \in \mathcal{A}} \mathbb{P}_\beta$. Since $\mathbb{Q}^\kappa$ is $(2^\kappa)^+$ -directed closed, it does not affect whether κ is measurable, and so κ is not measurable in $V^{\mathbb{Q}^\kappa}$. Since the forcing $\mathbb{Q}_{<\kappa}$ is an Easton support product in both V and $V^{\mathbb{Q}^\kappa}$ (and is therefore κ -c.c. in both V and $V^{\mathbb{Q}^\kappa}$), it follows by the argument given in the proof of Lemma 8 of [6] that κ is not measurable in $V^{\mathbb{Q}^\kappa \times \mathbb{Q}_{<\kappa}} = V^\mathbb{P}$. Thus, if κ is a measurable limit point of $\mathcal{K}$ in $V^\mathbb{P}$, it must be one in V also. As $\mathbb{P}^*$ can be factored as $\mathbb{Q}_0 * \dot{\mathbb{Q}}_1$, where $|\mathbb{Q}_0| = \omega$ and $\Vdash_{\mathbb{Q}_0} \text{“}\dot{\mathbb{Q}}_1 \text{ is } \aleph_1\text{-strategically closed”}$, the Gap Forcing Theorem of [18] and [19] implies that κ is measurable in V_0 as well.

Assume now that κ is supercompact in $V^\mathbb{P}$. Factor $\mathbb{P}^* * \dot{\mathbb{P}}$ as $\mathbb{Q}_2 * \dot{\mathbb{Q}}_3$, where $|\mathbb{Q}_2| = \omega$ and $\Vdash_{\mathbb{Q}_2} \text{“}\dot{\mathbb{Q}}_3 \text{ is } \aleph_1\text{-strategically closed”}$. Since $\mathbb{P}^* * \dot{\mathbb{P}}$ therefore admits a gap at $\aleph_1$, the Gap Forcing Theorem of [18] and [19] once again tells us that any supercompact cardinal in $V^\mathbb{P} = V_0^{\mathbb{P}^* * \dot{\mathbb{P}}}$ had to have been an element of $\mathcal{K}$ in V_0 . This, together with the remarks given in the first paragraph of the proof of the Main Theorem (which tell us that supercompactness is preserved in V), completes the proof of Lemma 16.

□

This completes the proof of our Main Theorem, Theorem 2.

□

Let us now turn to the Generalized Main Theorem.

Proof: We will show that the appropriate conclusions of the Main Theorem hold, more generally, for any class $\mathcal{A}$ of supercompact cardinals having finite Cantor-Bendixon rank. The proof will proceed by induction on the Cantor-Bendixon rank of $\mathcal{A}$. If $\mathcal{A}$ has rank 1, then it contains none of its limit points, and the previous theorem applies. Consider now a class $\mathcal{A}$ having rank $n + 1$. The first Cantor-Bendixon derivative $\mathcal{B} = \mathcal{A}^{(1)} = \mathcal{A} \cap \mathcal{A}'$ has rank n , and so by the induction hypothesis, there is a forcing extension $V_\mathcal{B} = V^{\mathbb{P}_\mathcal{B}}$ in which the cardinals of $\mathcal{B}$ become non-supercompact strongly compact cardinals, and all the supercompact cardinals of $\mathcal{K} - \mathcal{B}$ are preserved.

Our strategy is simply to apply the Main Theorem in the model $V_{\mathcal{B}}$ to the remaining cardinals in $\mathcal{A}$, that is, to the cardinals in $\mathcal{C} = \mathcal{A} - \mathcal{B}$. Since these are precisely the elements of $\mathcal{A}$ that are isolated in $\mathcal{A}$, the class $\mathcal{C}$ contains none of its limit points. Furthermore, in $V_{\mathcal{B}}$, the class of supercompact cardinals is precisely $\mathcal{K}_{\mathcal{B}} = \mathcal{K} - \mathcal{B}$, and $\mathcal{C}$ is a subclass of $\mathcal{K}_{\mathcal{B}}$. Thus, the Main Theorem applies in $V_{\mathcal{B}}$ to yield a further forcing extension $V_{\mathcal{A}}$ in which the cardinals of $\mathcal{C}$ become non-supercompact strongly compact cardinals and the cardinals of $\mathcal{K}_{\mathcal{B}} - \mathcal{C}$ remain supercompact. Furthermore, all the previously prepared non-supercompact strongly compact cardinals in $\mathcal{B}$ remain measurable limits of cardinals in $\mathcal{C} \subseteq \mathcal{A}$, since inductively, they satisfy GCH in $V_{\mathcal{B}}$, and so they remain strongly compact. They do not become supercompact again because the forcing of the Main Theorem does not create supercompact cardinals.

In summary, the cardinals in $\mathcal{K} - \mathcal{A}$ remain supercompact through both steps of the forcing, and the cardinals in $\mathcal{A}$ become non-supercompact strongly compact cardinals either in the first step, if they are limits of $\mathcal{A}$, or in the second step, if they are isolated in $\mathcal{A}$, respectively.

□

The Generalized Main Corollary now follows, because if the entire class $\mathcal{K}$ has finite Cantor-Bendixon rank, then so also does any subclass $\mathcal{A} \subseteq \mathcal{K}$, and so the conclusions of the Main Theorem would hold for any class $\mathcal{A}$. In particular, by cutting the universe off at some supercompact cardinal of Cantor-Bendixon rank n , one obtains a model with proper classes of supercompact cardinals of rank below n . When $n > 2$, for example, such a model would have a proper class of supercompact limits of supercompact limits of supercompact cardinals.

We conclude this paper by noting that another interesting generalization of the Main Theorem is obtained when there are no supercompact limits of supercompact cardinals and $\mathcal{A} = \mathcal{K}$. If we then use as $\mathbb{P}_{\kappa}$, for each $\kappa \in \mathcal{A}$, either of the partial orderings as described at the end of Section 2, we obtain a forcing extension where $V^{\mathbb{P}} \models$ “ZFC + There is a proper class of strongly compact cardinals + No strongly compact cardinal κ is supercompact + Every strongly compact cardinal κ is κ^+ supercompact and has trivial Mitchell rank with respect to κ^+ supercompactness”. This sort of model was first constructed on pages 113–114 of [6], but from the much stronger hypothesis

of “ZFC + GCH + There is an inaccessible limit of cardinals δ which are both δ^+ supercompact and a limit of supercompact cardinals”.

This generalizes the theorem from [4] (which is in itself a generalization of Theorem 2 of [5]). In this result, starting from $n \in \omega$ supercompact cardinals $\kappa_1, \dots, \kappa_n$, a model for the theory “ZFC + $\kappa_1, \dots, \kappa_n$ are the first n strongly compact cardinals + For $1 \leq i \leq n$, κ_i isn’t supercompact but is κ_i^+ supercompact” is constructed. Further generalizations, e.g., producing models in which there is a proper class of strongly compact cardinals, no strongly compact cardinal κ is supercompact, yet every strongly compact cardinal κ is κ^{++} supercompact and has trivial Mitchell rank with respect to κ^{++} supercompactness, etc., are also possible.
